Davide Tonelli

Portfolio

In the following it is shown a list of the major tasks I have been involved with while working at OPS Ltd.

The works are arranged in chronological order, starting from March 2015 up to now.

For each work a general description is provided which illustrates ONLY my personal contributions to the project, followed by a meaningful list of pictures and/or report excerpts.

1 Scheme design for a complex of 6 RC multi-storey buildings in Qatar

Being provided with architectural floor plans I started with sizing columns, cores and slabs. At a later stage, as usual during scheme design, I had to develop a number of options for prospective transfer structures at GF.

Also, as the building site has a high water table, I had to design different arrangements of tension piles at foundation level.

Transfer structures at GF

HAMAD 4D - Ground Floor Structure Proposal A

COLUMN:
It is 6000 mm tall, with a 9000 x 1000 mm cross section.

CANTILEVERING BEAMS:
Two beams cantilevering 4500 mm from the column. They are AT LEAST 2250 mm deep, possibly even tapered near the base.

LONGITUDINAL TRUSSES:
There are 4 20000 mm long and 2250 mm deep longitudinal trusses, two of which coupled at middle line. They are composed of an HD 400 x 677 standard profile, steel grade 355.

HAMAD 4D - Ground Floor Structure Proposal B

COLUMN:
It is 6000 mm tall, with a 9000 x 1000 mm cross section.

CANTILEVERING BEAMS:
Two beams cantilevering 4500 mm from the column. They are AT LEAST 2250 mm deep, possibly even tapered near the base.

LONGITUDINAL CONCRETE BEAMS:
There are 3 longitudinal beams, two lateral and one central. Lateral beams are 2250 mm deep by 1750 mm wide. The central beam is 2250 mm deep by 4500 mm wide. May be hollow.

CENTRAL TRUSS

LATERAL TRUSS

HAMAD 4D - Ground Floor Structure Proposal C

COLUMN:
It is 6000 mm tall, with a 9000 x 1000 mm cross section.

CANTILEVERING BEAMS:
Two beams cantilevering 4500 mm from the column. They are AT LEAST 2250 mm deep, possibly even tapered near the base.

LONGITUDINAL STOREY-DEEP TRUSSES:
There are 3 20000 mm long and 4800 mm deep longitudinal trusses, which are as deep as the first floor storey. The central truss is composed of an HD 400 x 818 standard profile, steel grade 355. The lateral trusses instead are composed of an HD 400 x 382 standard profile, steel grade 355.

The typology of truss can be agreed together.

LATERAL TRUSS

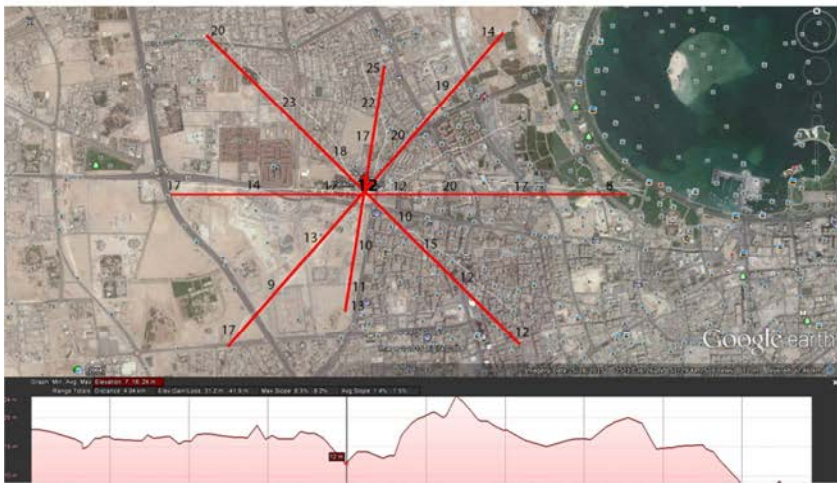

HAMAD 4D - Ground Floor Structure Proposal D

COLUMN:
It is 6000 mm tall, with a 9000 x 1000 mm cross section.

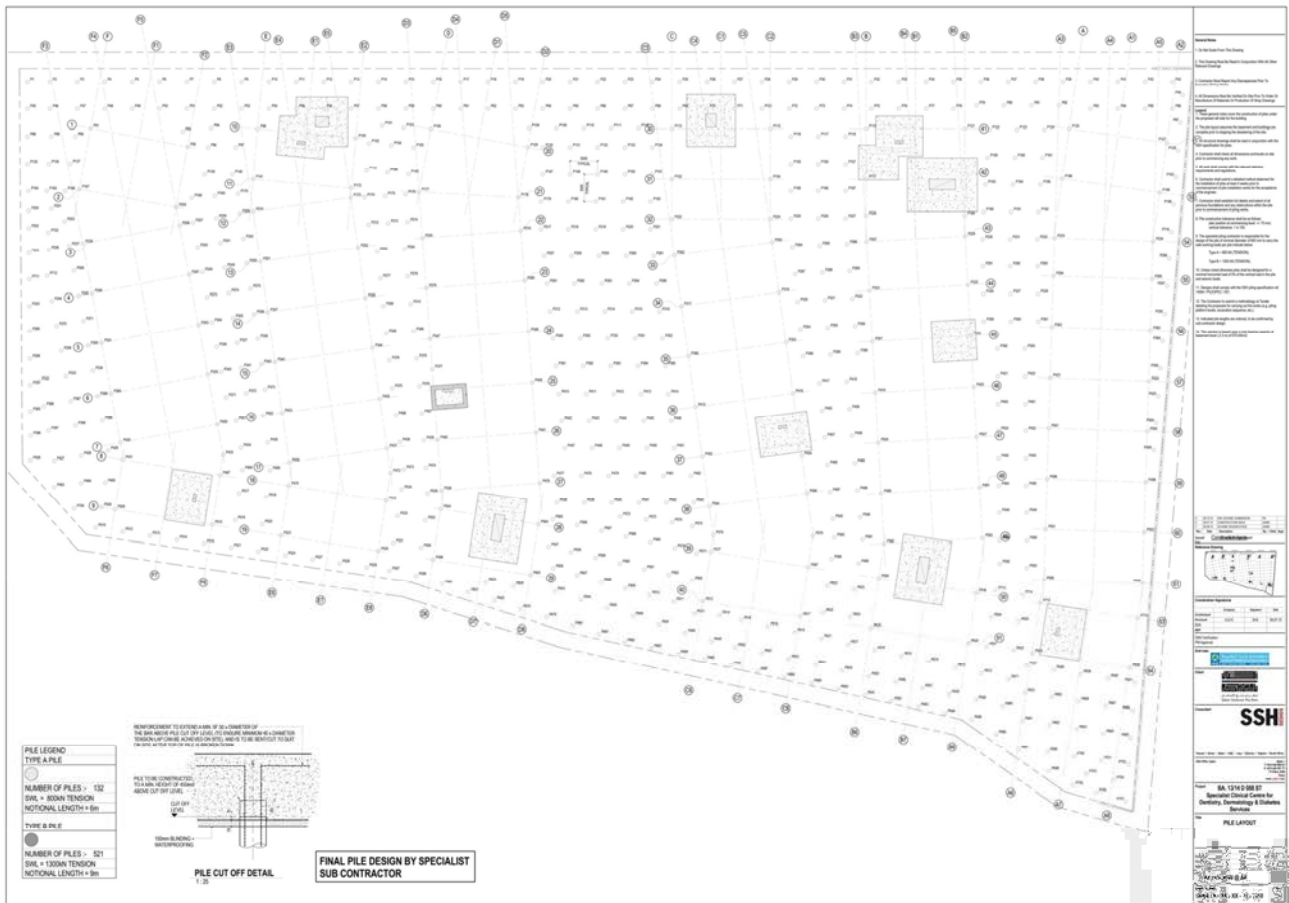

CANTILEVERING BEAMS:
Two beams cantilevering 4500 mm from the column. They are AT LEAST 2250 mm deep, possibly even tapered near the base.

LONGITUDINAL CENTRAL ARCH:
A reinforced concrete arch at ground floor level has been selected as a transfer structure for the central row of highly loaded columns. The span is 20 m with a maximum clearance of 4.7 m.

LONGITUDINAL LATERAL TRUSSES:
As in proposal C, the lateral transfer structures are trusses at first floor level, but with a different static scheme in order to allow higher transparency. They are composed of an HD 400 x 592 standard profile, steel grade 355.

Altitude study of the site (left) and water table on basement

Basement raft with tension piles: general arrangement

2 Detailed design for a RC multi-storey buildings in Qatar

At a later stage I carried out the detailed design for the concrete members of one of the aforementioned six buildings.

The whole building was modelled in the F.E. program Robot, then tailor-made spread-sheets were set up in order to carry out the structural design.

LEGEND

Ast and Asl refer to a full width column strip, also on the edge and corner columns!

HOLES

If there are holes near a column, the control perimeter must be reduced accordingly. The part of control perimeter contained between the tangents to the outline of the hole - drawn from the column centre - must be computed and taken out from u_1 . This can be computed by hand and subtracted from u_1 of the selected type of column, one-off. This being done, the rest of the check keeps unvaried.

Green = Input data.
Yellow = Results.

Slab punching shear checks

3 Detailed design for a long span steel canopy in Qatar

All the buildings composing the Hamad Medical Centre are linked by a lightweight steel canopy with a non-trivial geometry.

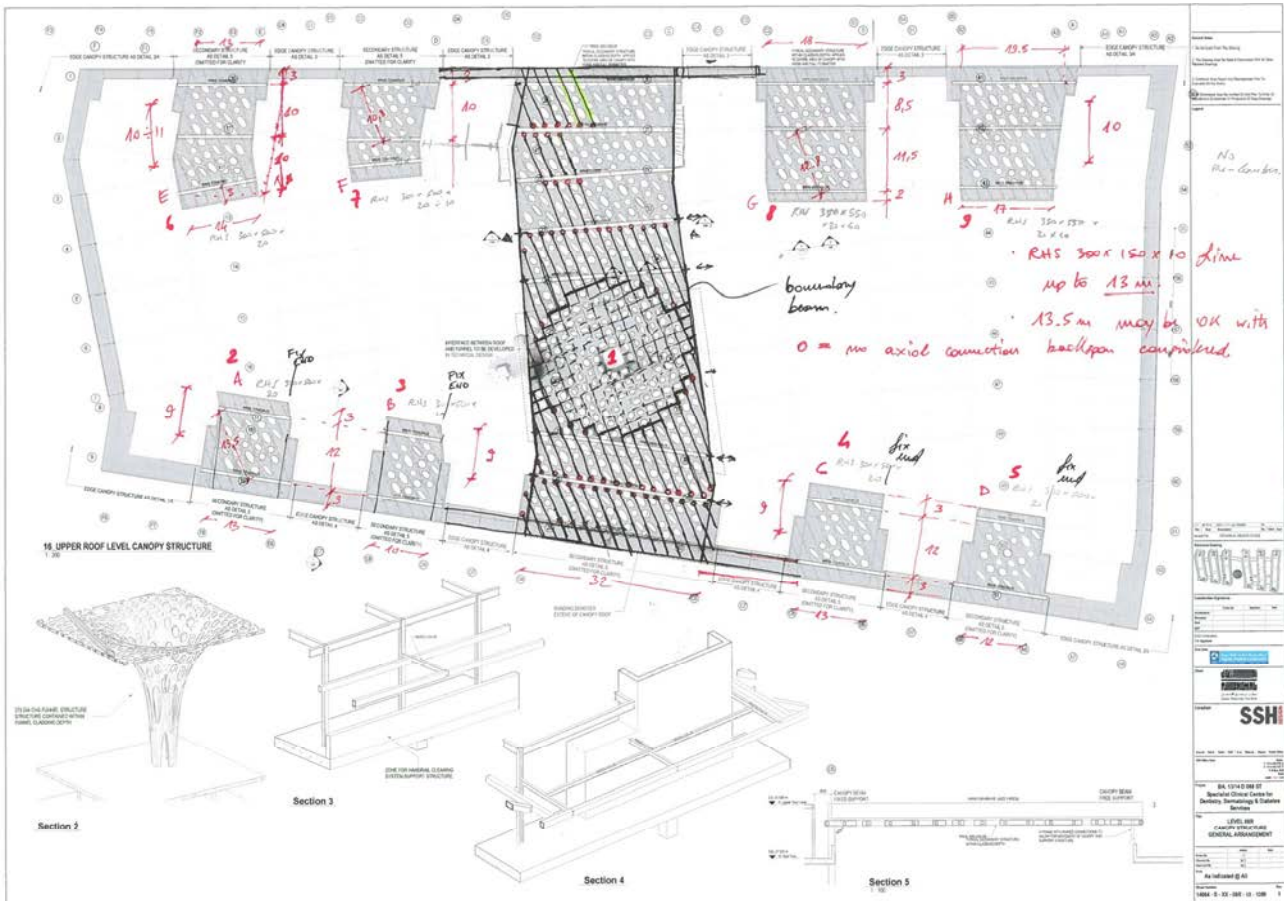

I developed its design from the very early stage up to the technical design phase, in close collaboration with the architects.

The central part of the canopy is roughly 100 m long by 30 m wide and is supported by transversal fabricated box beams. At its center a vortex structure connects it to the ground, right in front of the main building entrances.

The whole geometry was modelled in Rhino. Automated spread-sheets were then necessary in order to carry out the structural checks, due to the considerable number of members and load combinations.

4 Detailed design for the steel enclosure roofs of 6 RC multi-storey buildings in Qatar

Each of the roof slabs of the buildings composing the Hamad Medical Centre hosts essential MEP machinery and hence needs a bespoke enclosure roof.

I designed lightweight steel frames to support them. Although similar to each other, separate design had to be carried out because of cutbacks and recesses that made each of them unique. These cutbacks were required by the architect and led to the introduction of a number of additional bracings at the ends of the roof structures.

5 Detailed design of a 15 m tall totem structure in the Opera House area, Dubai

The project of the Opera House in Dubai envisages a set of 8 “totems” within the plaza adjacent the main Opera House building.

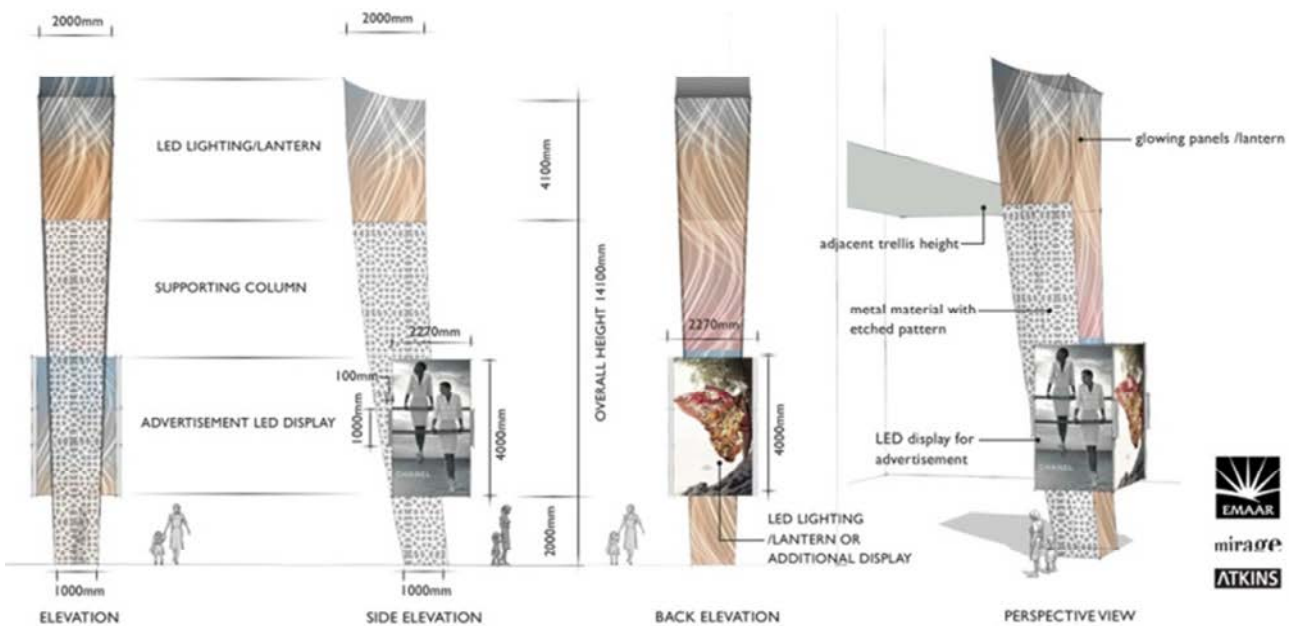

These totems are intended to be lightweight steel columns endowed with secondary frames devised to connect provisional, interchangeable installations and posters.

As the figures below show, the totems are roughly 15 m tall and 1 m wide at the base, whereas their centre line is curved.

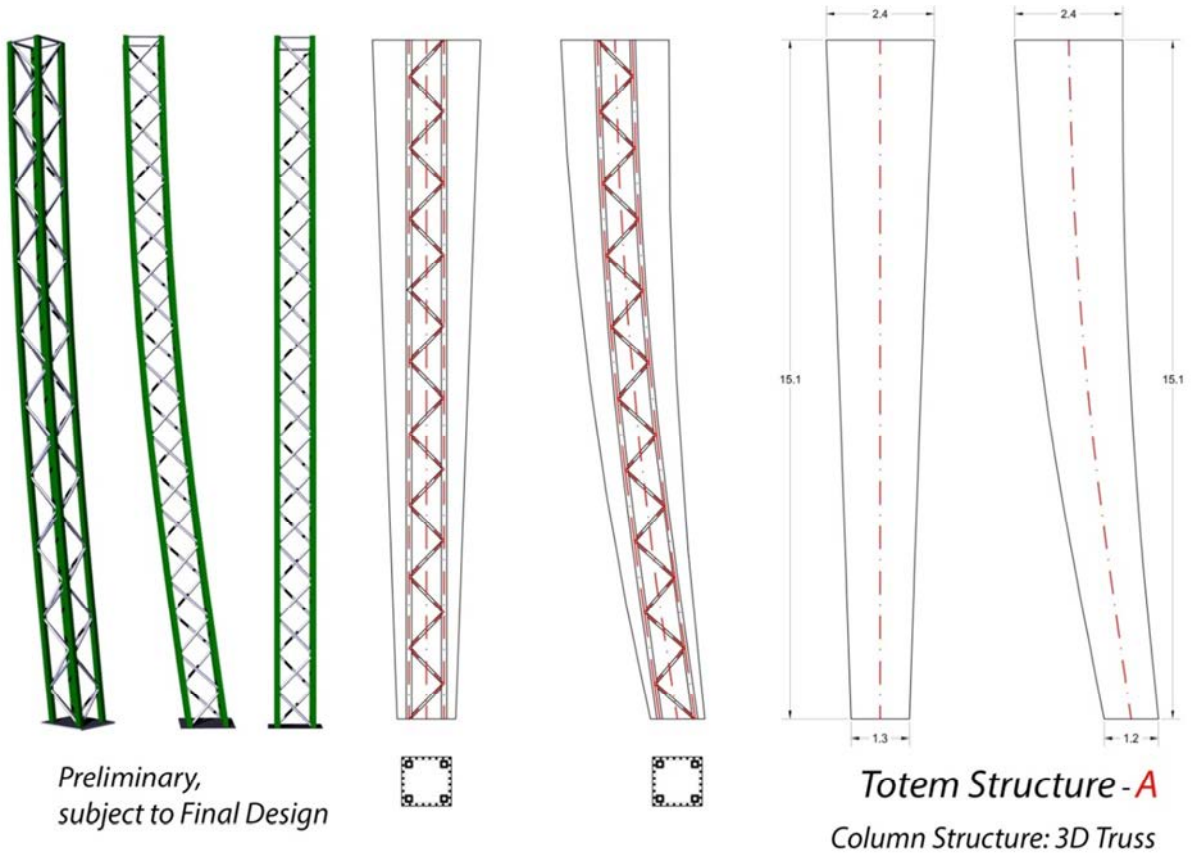

I developed three scheme options for their structure, one of which is reported below. Additionally, I handed out the holding down bolts arrangement for construction.

Holding down bolts: arrangement issued for construction

6 *Technical review of the remedial works for a multi-storey car park in Oman*

I produced a number of technical reports over a period of 8 months regarding the technical review of remedial works for a multi-storey concrete car park in Oman.

As shown in the figure below, the starter bars in the P2 columns were not properly anchored. As a consequence the construction was stopped at P2 level and a third party consultant was appointed to devise remedial works. They decided to demolish the P2 columns, their footprint within the PT slab as well as the P1 column heads. Then a corbel was built on the slab underside to carry the storey shear and the columns were re-cast with appropriate reinforcement.

OPS Ltd. were appointed for the technical review of the aforementioned remedial works. I carried out several checks according to various codes (ACI 318M-11, EC2, BS 8110) as well as by applying the plasticity theorems, in order to prove that the reinforcement provided in the corbel was not sufficient to provide the required factor of safety.

OPS Ltd. and the third party consultant could not reach an agreement and the consultant decided to take full responsibility over it.

Wrong anchoring of P2 starter bars

Corbel reinforcement

Application of the plasticity theorems in order to work out the corbel ULS load factor

Parametric analysis on the relationship between slab-corbel relative stiffness and corbel load bearing capacity

7 Scheme design for a multi-storey car park in Qatar

Halfway in the design process of the Hamad Medical Centre in Qatar, the client decided to build a multi-storey car park in a plot next to the buildings site, in order to increase the parking capacity already provided by the basement car-park.

As a peculiarity, because the space near the site was limited the car park had to overhang an existing MEP building.

I carried out the scheme design, providing three general options involving RC, PT and PC slabs, respectively. I also worked out four alternative options for the area overhanging the existing building, namely 21 x 25 m in plan, where the columns could only be located along the perimeter. Among the options there were either a steel girder or a truss at P2 level, or composite beams at all floors, all of them being 9 m spaced apart.

The design of the composite beams proved to be very challenging as the long span (21 m) and the high load and beams spacing stretched the design to its limit. Therefore, in order to fine tune the beams design, I set up bespoke spread-sheets.

OPS
STRUCTURAL ENGINEERING

HAMAD EXTERNAL CAR PARK, PRELIMINARY DESIGN RESULTS - OVERALL CAR PARK										
Option 1				Option 2				Option 3		
2-ways RC flat slab				2-ways PT flat slab				1-way Pre Cast slab

8 Scheme design for Riyadh Western Metro Station

OPS Ltd. were appointed for the concept design of the Riyadh western metro station. The architectural project involved two long span roofs, the longest of which being in excess of 110 m.

I produced two options involving a two hinged arch with fabricated box section and a trussed two hinged arch. The latter turned out to be more effective as the secondary members necessary to support the roof (as per architectural design) could be effectively used as truss diagonals, thus reducing the overall structural mass.

Two options to cover the station 110 m span

RIYADH METRO WESTERN STATION CANOPY - FEASIBILITY STUDY

9 Detailed design for the façade of a 150 m tall tower in Saudi Arabia

OPS Ltd. were appointed for the design of a tower in Saudi Arabia, 150 m tall. I collaborated with a senior façade engineer to develop the tower façade from scheme to detailed design.

First thing the façade system was selected, with vertical mullions 1.5 m spaced apart and 1-way spanning glazings. Then I sized all the glass elements according to the publication “Structural use of glass in buildings” by the Institution of Structural Engineers and the EC code draft prEN 13474-2012. The elements involved IGUs, spandrel laminated panels, vertical and horizontal beams. For each of them I set up a tailored spread-sheet. Then I schemed and designed all of the connections between glass elements and building structure (see figures below).

Eventually, as the back and roof of the tower must accommodate PV panels, I designed a modular frame 6 x 3 m wide to support them. I also selected the connection devices to attach the PV panels to the frame, in such a way that the whole frame is assembled in plant and then hauled on site, ready to be fastened onto the building structure (see last figure).

10 Checks and remedial works for a complex titanium cladding in Iraq

A new Cultural Centre has recently been built in Iraq. The complex is made up of four buildings with a faceted skin, covered by a very elaborate cladding.

At a very late stage in the construction process the cladding system adopted proved to be unsuitable for the purpose. In particular both the structural decking and the cladding panels appeared to be too flexible and the connection device between them badly conceived. Additionally, the overall quality of the cladding work installed looked poor.

OPS Ltd. were appointed to investigate the root causes of the poor performances of the cladding and to find solutions. I was entrusted with the task.

I started by identifying the main reasons of concern: i.e. the capacity of the metal decking, the pedestal screwed connection onto the deck, the stiffness of the cladding panels, the glued connection between cladding panels and stiffeners, the stiffeners position and the quality of the workmanship.

Regarding the metal decking, I first worked out its effective width under point load from the pedestal (see figure below). Then I computed its effective section under pressure and suction loads according to EC 1993. Eventually I carried out numerical buckling tests with the constrained finite element method and devised physical testing to validate the results. This is an extensive work and it is still ongoing.

Cultural Centre architectural project and cladding close-up

Cassette bracket fixings

Pedestal to metal decking connection

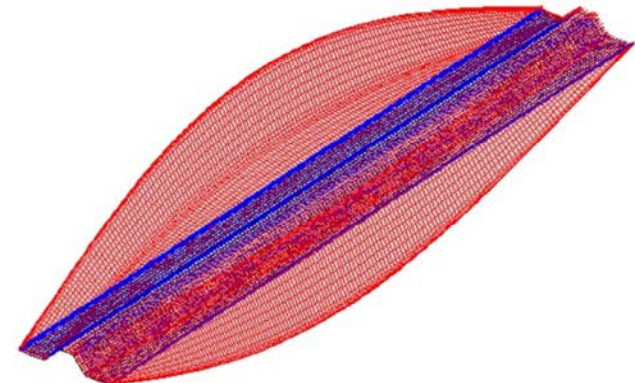

Evaluation of deck effective width under pedestal point load

	M_{ED} (kNm)	$M_{B,RD}$ (kNm)	$M_{ED} / M_{B,RD}$
SUCTION	-3.16	-0.99	3.2
PRESSURE	3.45	1.01	3.4

Evaluation of effective section according to EC 1993-1-3 and 1993-1-5

Deck buckling analysis under pressure (right) and suction load (left), using the constrained finite element method

11 Technical review of a long span timber roof of a pool in UK

A swimming pool covered by a series of 50 m span glulam frames has recently been built in UK. Not long ago the completion of works the roof started exhibiting high as well as unexpected permanent deformations at the ridge, the causes of which are not clear yet.

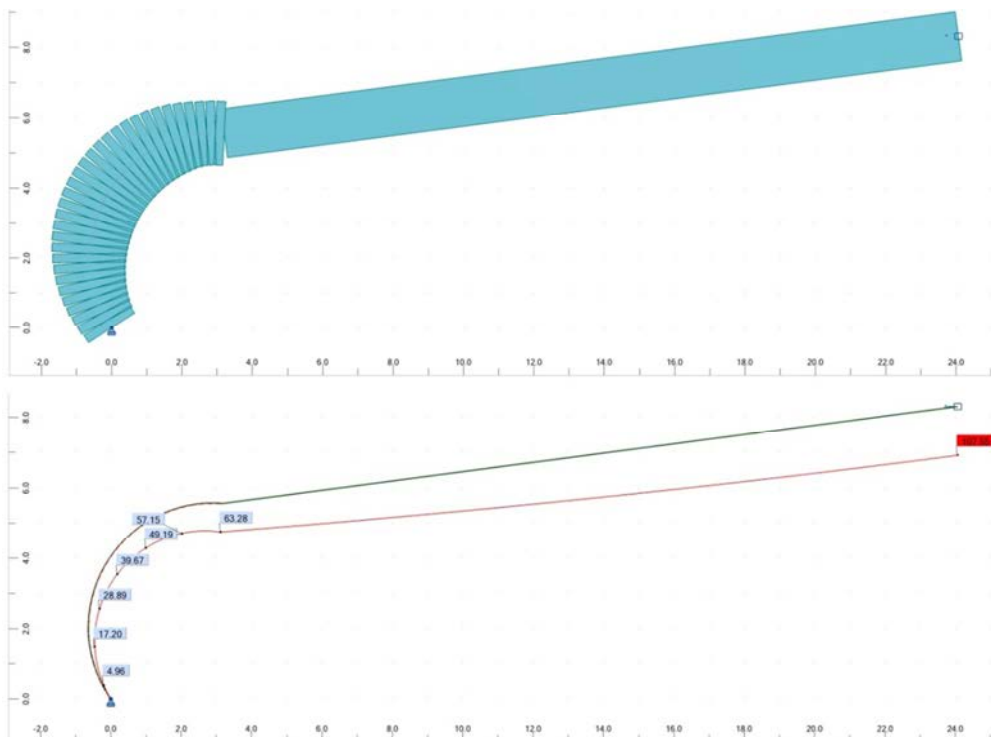

OPS Ltd. were appointed to investigate the root causes and to find solutions.

I went through all the designer and contractor documentation and carried out numerical parametric testing in order to point out the effect of several parameters such as shrinkage, change in moisture content, manufacturing tolerances, foundations stiffness, etc... onto the structure's behaviour.

The work is still ongoing.
