

# SISTEMI EMBEDDED

Programming the DE10-Lite Basic Computer:  
playing with parallel ports (or PIO)

Federico Baronti

Last version: 20180314

# Putting into practice (1a)

- Write a program that turns on a single LED among LEDR7-LEDR0 and makes the position of the on-LED rotate with a period of around 500 ms. Make the activation and direction of the rotation controllable by the pushbutton KEY0, as follows:
  - Each pressure of KEY0 changes the rotation state cyclically from OFF to LEFT to RIGHT
  - The program must be sensitive to the edges originated by the release of the pushbutton KEY0

# Putting into practice (1b)

- Hints:
  - Recognize pushbutton releases through the EVENT register of the relevant Parallel Port (or PIO)
  - Store the LEDR7-LEDR0 status on a 8-bit unsigned variable
  - Use <<, >> for left and right rotation (be careful to manage the all-zero situation)
  - Use a finite state machine (Moore model) to:
    - update the rotation state according to the KEY0 events
    - generate the new LEDR7-LEDR0 status through a *switch* instruction that scans the rotation state

# Putting into practice (1c)

- Hints: Pushbutton Parallel Port

Address	31	30	...	4	3	2	1	0	
0xFF200050	Unused						KEY <sub>1-0</sub>		Data register
Unused	Unused								
0xFF200058	Unused						Mask bits		Interruptmask register
0xFF20005C	Unused						Edge bits		Edgecapture register

- To clear an *Edgecapture register* bit write 1 into it
  - This behavior is obtained when the *bit-clearing for edge capture register* is enabled; otherwise the register is cleared all at once when writing any value to it

# Putting into practice (1d)

- Hints:
  - Use the `Wait_ms()` function to generate the rotation period

```
/* delay generation */
#define CYCLES_PER_MS 574
/* value hand tuned to achieve around 1 ms resolution
 * for the DE10-Lite Basic Computer (code optimization OFF)
 */
void Wait_ms(unsigned int time_ms)
{
    int i,j;
    for(j=0; j<time_ms; j++)
    {
        for(i=0; i<CYCLES_PER_MS; i++) {}
    }
}
```

- What does it happen if the LEDR7-LEDRO status is stored in a signed variable?

# Putting into practice (2)

- **Faster click game:**

- Detect which of KEY1 and KEY0 is pressed first after turning on one of the RED LEDS
- Make the interval time between two consecutive switching on of the LED random
- Make also the RED LED position random
- Signal which KEY has been pressed first using HEX5
- Display the number of times KEY1 has been pressed first on HEX3-HEX2 and KEY0 on HEX1-HEX0
- Use one SLIDER to start/stop the game and reset the scoring

# Putting into practice (3a)

- **Week day**

- Show on RED LEDS 6..0 the day of the week of an arbitrary date after 1582 (Gregorian calendar), which is set using KEY1..0 and displayed on the 7-seg displays
- Use KEY0 to move circularly from day to month to year and KEY1 to change the selected digit of the date
- To show the selected digit of the date turns on the point on the corresponding 7-seg display

# Putting into practice (3b)

- **Week day**

- How a C++ program for a PC using standard I/O streams looks like:

```
// gionosett.cpp
#include <iostream>
using namespace std;
int main(){
    int giorno, mese, anno, sett;
    cout << " Scrivi una data nel formato giorno mese anno\n";
    cin >> giorno >> mese >> anno;
    if (mese <= 2) {
        sett = (anno+31*(mese-1)+giorno+(anno-1)/4-
3*((anno+99)/100)/4)%7; }
    else {
        sett = (anno+31*(mese-1)+giorno-(4*mese+23)/10+anno/4-
(3*(anno/100+1)/4))%7; }
    // ...
```

# Putting into practice (3c)

- **Week day**

- How a C++ program for a PC using standard I/O streams looks like:

```
cout << "Il giorno " << giorno << '/' << mese << '/' << anno << " cade di ";  
    switch(sett) {  
        case 0: cout << "sabato\n"; break;  
        case 1: cout << "domenica\n"; break;  
        case 2: cout << "lunedì\n"; break;  
        case 3: cout << "martedì\n"; break;  
        case 4: cout << "mercoledì\n"; break;  
        case 5: cout << "giovedì\n"; break;  
        case 6: cout << "venerdì\n"; break;  
    }
```
