# Stochastic Activity Networks ( SAN )

The Stochastic Activity Networks are a wide-ranging and complex extension to Petri-Nets

Petri Net = places + transitions + enabling conditions + firing rules

Stochastic Petri Net = Petri Net + stochastic transition delay

Stochastic Activity Network = Stochastic Petri Net + stochastic transition outcome  
+ advanced enabling condition + advanced firing rules

# SAN in Möbius tool 1/2

NOTE: the terms **activity**, **transition** and **action** will be used interchangeably

Transitions may be timed or instantaneous

Enabling conditions are defined with input gates associated with transitions

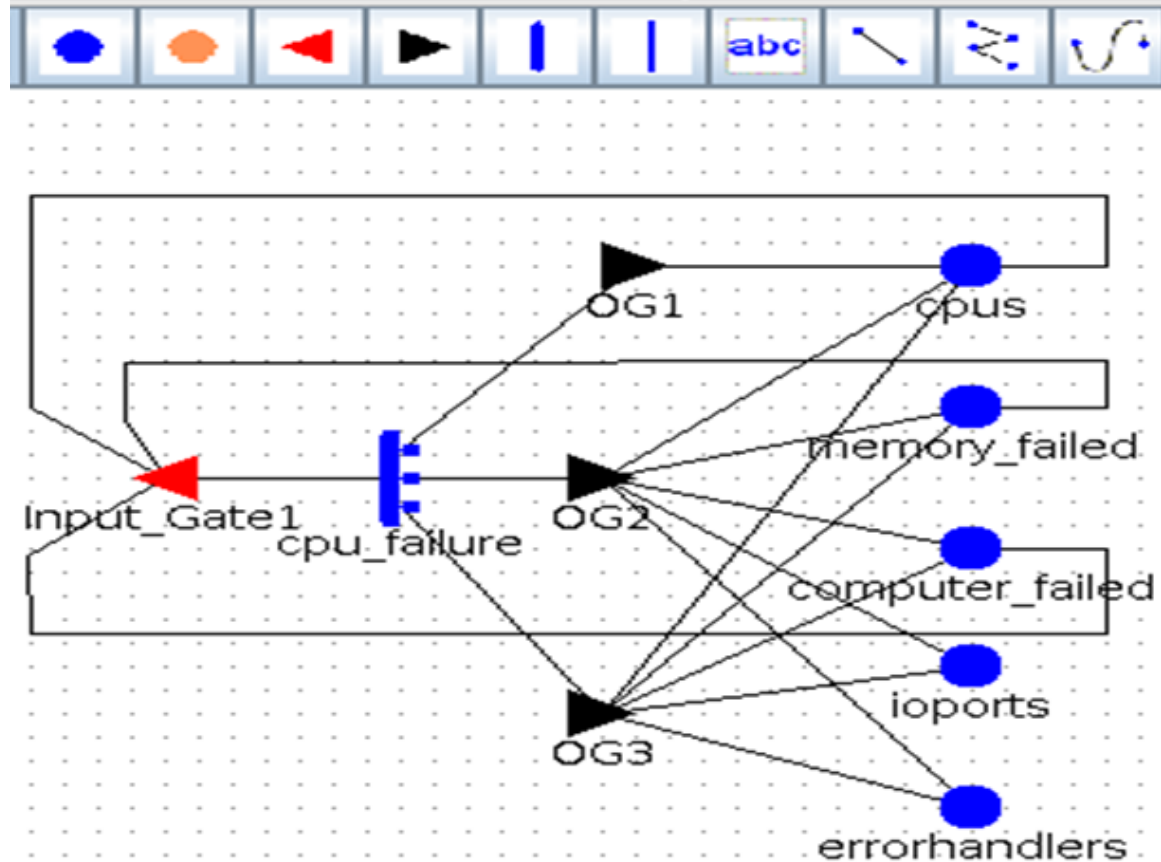

Firing rules: user-defined functions specified in input or output gates

# SAN in Möbius tool 2/2

Stochastic transition outcome: Alternative results of a transition can be specified as mutually exclusive cases associated with the transition

Each case has a probability defined by a function of the marking ( it may be a constant )

**Atomic and Composed model, reward, study, transformer and solver**

are used in the same way they are used for Fault Tree analysis.

Möbius allows to evaluate a Performance Variable

**Steady State**

**Transient (instant of time)**

# Failure-Detection-Repair

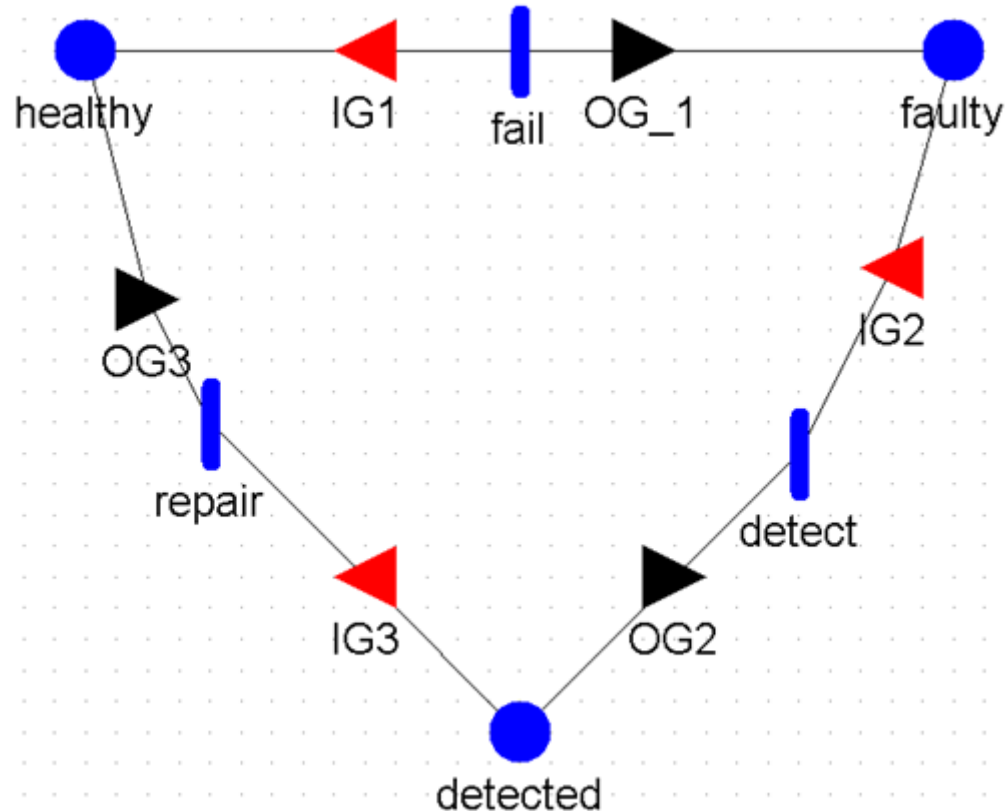

- Two identical CPUs
- **Failure of the CPU:**  
exponentially distributed  
with parameter  $\lambda$
- **Fault detection:**  
exponentially distributed  
with parameter  $\delta$
- **CPU repair:**  
exponentially distributed  
with parameter  $\mu$

Evaluate  
Availability of  
the system  
during steady  
state,  
considering that  
the system is  
working if at  
least one CPU is  
healthy

# Atomic Model

Remember to edit three global variables

(  $\lambda$ ,  $\mu$  and  $\delta$  )

Set the initial state for places )

( healthy = 2, faulty = 0, detected = 0 )

Set the rate of each event as the number of token in the input place times the rate of the event

Set the input enabling function, stating that the activities are enabled if there is at least one token in the input place

Set the output function, so that it decreases the number of tokens in the input place and increases the ones of the output place by one

# Fail example

## Input Predicate

```
healthy->Mark() > 0
```

## Output Function

```
faulty->Mark() ++;  
healthy->Mark() --;
```

Name:

fail

Time distribution function:

Exponential

1

Rate

```
return lambda*healthy->Mark();
```

Case quantity:

1

Case 1

1

# Reward model

- Create a performance variable called **availability**.
- Express its **reward function** according to the condition of correctness of the system.
- Set a steady-state **Time** option with default configurations.

## Available State Variables (double click to insert)

```
ex1_san->healthy  
ex1_san->faulty  
ex1_san->detected
```

## Reward Function

```
if( ex1_san->healthy->Mark() > 0) return 1;  
else return 0;
```

# Study model

Type:	double
Initial	<input type="text" value="0.1"/>
Final	<input type="text" value="0.5"/>
	<input checked="" type="radio"/> Additive
	<input type="radio"/> Multiplicative
	<input type="radio"/> Exponential
Increment	<input type="text" value="0.2"/>

Set a **range study** model where all the three rates vary from 0.1 to 0.5 with a step of 0.2.

All the possible combinations lead to **27 experiments**

# Transformer and Solver

Again use the State Space Generator ( NOT Symbolic) as transformer

Then, in order to evaluate the steady state behavior choose a Steady State solver.  
For simplicity select the Direct Steady State Solver.

The behavior of different solvers can be found in the Möbius wiki.

Experiment 1:

**lambda** = 0.1, **delta** = 0.1, **mu** = 0.1 è Availability = 0.55555

Experiment 14:

**lambda** = 0.3, **delta** = 0.3, **mu** = 0.3 è Availability = 0.55555

Experiment 4:

**lambda** = 0.3, **delta** = 0.1, **mu** = 0.1 è Availability = 0.2653

Experiment 3:

**lambda** = 0.1, **delta** = 0.5, **mu** = 0.1 è Availability = 0.702

# Exercise

A computer is idle, busy, or failed;  
jobs arrive at a rate  $\alpha$  ;

1000

jobs are completed at a rate  $\beta$  ;

10000

the computer fails at rate  $\lambda_i$  when idle;

1.0E-7

the computer fails at rate  $\lambda_j$  when busy.

From  $1 \times 10^{-6}$  to  $5 \times 10^{-6}$

**Evaluate availability and then the reliability**
